

ALGORITHM 1: High-Frequency Baseline Discrete Trading Agent

(policy-gradient update; PP0 is one option)

Input : Historical prices $\{P_t\}$, fee c , epochs E , days-per-epoch K

Output : Optimised policy parameters θ^*

```
=====

1. Initialise policy  $\theta$  and value  $\phi$  randomly
2. FOR epoch = 1 to  $E$  DO
3.     FOR each trading day (episode)  $k = 1$  to  $K$  DO
4.         Initialise state  $s_0 = [\Delta P_0, h_0 = 0]^T$ 
5.         Initialise buffer  $B = \{\}$ 
6.         FOR minute  $t = 0$  to  $T-1$  ( $T = 390$ ) DO
7.             Compute  $\pi_\theta(a_t | s_t)$ 
8.             Sample  $a_t \sim \pi_\theta$  where  $a_t \in \{0:\text{Hold}, 1:\text{Buy}, 2:\text{Sell}\}$ 
9.             IF  $a_t = 1$  THEN  $h_{t+1} = 1$  (Buy / Long)
10.            IF  $a_t = 2$  THEN  $h_{t+1} = 0$  (Sell / Cash)
11.            IF  $a_t = 0$  THEN  $h_{t+1} = h_t$  (Hold)
12.            Observe  $\Delta P_{t+1} = (P_{t+1} - P_t) / P_t$ 
13.            Reward  $r_t = (h_t \cdot \Delta P_{t+1}) - c \cdot |h_{t+1} - h_t|$ 
14.            Next state  $s_{t+1} = [\Delta P_{t+1}, h_{t+1}]^T$ 
15.            Store  $(s_t, a_t, r_t, s_{t+1})$  in  $B$ 
16.        END FOR
17.    END FOR
18.    Update  $\theta$  by policy gradient / PP0 loss on  $B$ 
19.    Update value network  $\phi$ 
20. END FOR
21. RETURN  $\theta^*$ 

=====
```

Iteration 1 only – 3 actions, binary holding, one stock, one day = one trajectory
